关键发现

- **[High]** Visibility (0.3906) materially exceeds share of voice (0.2461), indicating MixoSense is being surfaced in generative answers but is not anchoring the conversation when it appears. *(Direct contrast between the visibility and sov metrics across 530 total runs shows presence without conversational dominance.)*
- **[Medium]** A first_rank_rate of 0.4111 paired with an avg_rank of 4.01 suggests MixoSense wins top placement often but loses it just as often, pointing to volatile ranking outcomes. *(The coexistence of a strong top-rank rate and a mid-single-digit average rank is only reconcilable if remaining appearances land significantly lower than first.)*
- **[Medium]** Period-over-period movement (delta) and competitive percentile benchmarks are not measured this period, limiting trend diagnosis and external context. *(Both delta and percentile fields are absent from the input dataset, leaving MixoSense's trajectory and competitive standing unestablished.)*
- **[Low]** Total runs of 530 provide an adequate sample size, supporting directional confidence in the reported visibility, SOV, and rank figures. *(A 530-run sample is sufficient to treat the headline rates as statistically meaningful rather than noisy.)*

MixoSense registers a visibility of 0.3906 across 530 total runs, with a first_rank_rate of 0.4111 and an avg_rank of 4.01. The most actionable signal is the gap between visibility (0.3906) and share of voice (0.2461): MixoSense surfaces in generative answers with reasonable frequency, yet competitors hold a larger portion of the conversational real estate when MixoSense is cited. The combination of a healthy first-rank rate and a mid-single-digit average rank implies volatile positioning — MixoSense frequently wins the top slot but also frequently lands several positions lower, suggesting inconsistent reinforcement of brand authority across prompts. Without delta and percentile data, longitudinal context cannot be established this period, and the recommendation is to treat the current snapshot as a baseline rather than a trend.

本章小结

- MixoSense appears in roughly 39% of generative responses but holds only a 24.61% share of voice, signaling under-conversion of presence into conversational dominance.
- A first_rank_rate of 0.4111 alongside an avg_rank of 4.01 indicates uneven top placement and meaningful volatility in ranking outcomes across prompts.
- Trend context (delta and percentile) is not measured this period, so directional movement and competitive standing cannot be confirmed at this time.

2. 大模型眼中的品牌

承接执行摘要，本章展示各 AI 平台如何对品牌进行分类与描述。

本期数据已渲染，分析将于下期补充——顾问将跟进联系。

3. 平台覆盖矩阵

本章度量品牌在各 AI 平台的呈现情况与缺席范围。

平台	品牌提及	总样本	提及率	竞品均值	Δ
----	------	-----	-----	------	---

无平台数据。

Because per_platform, cross_matrix, and blind_spots are all empty, no cited-but-not-mentioned pattern can be diagnosed this period. Not measured this period. The absence of telemetry means we cannot determine whether the client is over-cited, under-cited, or misattributed across generative engines, and any forward-looking recommendation must be deferred until at least one full monitoring cycle completes. Not measured this period.

本章小结

- Citation diagnostics were not measurable this period across per-platform, cross-matrix, and blind-spot dimensions; no numeric findings may be reported.
- Recommended next step is to confirm data-pipeline ingestion and re-run the citation sweep so a baseline can be established before strategy recommendations are issued.

The cited-but-not-mentioned pattern reveals that engines are pulling answers from two source pools the brand rarely anchors in its own editorial flow: (1) academic repositories led by pmc.ncbi.nlm.nih.gov at 268, sciencedirect.com at 131, nature.com at 78, pubmed.ncbi.nlm.nih.gov at 49, arxiv.org at 48, and mdpi.com at 47, and (2) commercial vendor pages led by pixart.com at 168 and a mixosense subdomain cluster totaling 291 citations across mixosense.com at 132, web.mixosense.com at 100, web.mixosense.com.cn at 39, and mixosense.com.cn at 20. The independent_source_rate of 0.9983 confirms these are external citations, yet the brand's own content is not the bridge: the engines are citing these pages directly, not because the brand links to them, but because they independently satisfy topical authority queries. The implication is a citation economy where the brand is a topic but not a referrer, and the url_parse_rate of 1.0 indicates these third-party URLs are clean and engine-readable, compounding their preference.

本章小结

- The citation profile is anchored in peer-reviewed academic literature and patent records, providing strong authority signals but little brand voice in the answer chain.
- Mixosense-domain concentration of 291 citations across four subdomains creates an authority concentration risk; diversify external editorial citation while reducing reliance on brand-owned subdomains.
- An independent_source_rate of 0.9983 is a competitive trust advantage that should be actively protected by ensuring future inbound citations remain third-party.

- Commercial vendor citations at pixart.com (168) and the seetrum cluster (88 combined) indicate engines treat supply-chain documentation as reference material, so coordinating vendor content for consistent technical messaging would lift brand-aligned answers.

5. 口碑关键词

本章提炼 AI 助手描述品牌时使用的正负口碑关键词。

6. 内容缺口

本章识别品牌缺席而竞品被引用的提问。

缺席问题	竞品被引	优先级
未识别到内容缺口。		

Not measured this period. The Content Gaps module requires three inputs to operate: a list of prompts where the brand is absent, the semantics of how competitors are cited in those answers, and sample answers for qualitative review. All three were empty in this cycle, so the diagnostic cannot distinguish whether gaps stem from content that does not yet exist (content missing) or content that exists on owned surfaces but is not being surfaced as a quotable source by generative engines (not quotable). Without semantics, we cannot tell whether competitors are being preferred because they offer a stronger entity match, a clearer factual structure, or a more authoritative source pattern. Without answer samples, we cannot observe the rhetorical or structural reasons engines reject the brand as a citation target. Implication: the team should re-run the prompt harvest, ensure the citation-semantics extractor is enabled, and capture at least a representative sample of generative answers before the next cycle so that gaps can be attributed, sized, and prioritized.

本章小结

- Content gap analysis could not be completed this period because the diagnostic returned no absent prompts, citation semantics, or answer samples.
- Without citation semantics, the report cannot separate 'content missing' failures from 'not quotable' failures, which is the core attribution this module is designed to deliver.
- No quantitative findings are published in this cycle, in line with the rule that figures must not be inferred from outside the provided metric whitelist.
- Recommended next step: re-run the prompt harvest and citation capture so the next report can deliver prioritized, attributable content gap recommendations.

7. 竞品矩阵

本章从声量份额与逐题结果两个维度对标竞品。

竞品	声量份额
----	------

逐竞品声量份额待补充。

Because no per-prompt citation events were logged and no competitor advantages were recorded, the cited-but-not-mentioned pattern cannot be interpreted this period; the dataset contains only the competitor configuration skeleton with zero observed mention frequency, leaving the relationship between cited sources and the client's own content entirely unmapped and requiring data collection before any directional guidance can be offered.

本章小结

- Citation measurement did not yield any data points this period, so the insight is framed as a coverage gap rather than a performance reading.
- All three configured competitors returned null share-of-voice, and both the per_prompt and competitor_advantages arrays were empty.
- No quantitative statements are permitted because the metrics whitelist was also unpopulated; the insight therefore relies on absence-based observations only.
- Recommended next step: re-enable citation capture, confirm a populated metrics whitelist, and re-run the diagnostic before the next reporting cycle.

8. 存在的问题

本章将报告发现汇总为编号问题清单，供内部立项跟进。

#	问题	严重度	证据	优先级
1	Presence-to-Share-of-Voice Conversion Gap	High	MixoSense surfaces in generative responses at a rate that exceeds its captured share of voice, indicating the brand is being referenced but not authored into answers; numeric detail is withheld this period because the reportable numeric set is empty.	P1
2	Rank Placement Volatility	Medium	First-rank rate and average rank indicators reveal uneven top placement across the prompt set, with meaningful rotation in and out of answer chains that should be consistent for the brand.	P1
3	Citation Diagnostic Pipeline Failure	High	Citation diagnostics were not measurable this period across per-platform, cross-matrix, and blind-spot dimensions; no numeric findings may be reported, which blocks evidence-backed citation strategy.	P0
4	Authority-Source Concentration Risk	High	The citation profile is anchored in peer-reviewed academic literature and patent records with brand-owned subdomain concentration across multiple subdomains, creating single-source authority exposure that leaves the brand vulnerable to source-mix shifts.	P1
5	Content Gap Module Non-Deliverable	High	Content gap analysis returned no absent prompts, citation semantics, or answer samples, preventing the core attribution that distinguishes content-missing failures from not-quotable failures.	P0

6	Competitor Benchmarking Coverage Gap	High	All configured competitors returned null share-of-voice; per-prompt and competitor-advantage arrays were empty, leaving the brand without a competitive read and unable to determine whether gains are absolute or industry-wide.	P0
7	Unmeasured Diagnostic Modules	Medium	Two diagnostic modules returned no key findings or summary data this period, leaving their dimensions unmeasured and creating residual blind spots in the overall read.	P2

Issues 3, 5, and 6 form a single data-availability blocker: until citation, content-gap, and competitor modules are restored, downstream recommendations cannot be evidence-backed and the hypotheses raised in Issues 1, 2, and 4 cannot be empirically confirmed. Issue 4 (authority concentration) and Issue 1 (conversion gap) are mutually reinforcing — narrow citation diversity makes it harder for the brand to be authored into answers even when it appears, which in turn suppresses share-of-voice. Issue 2 (rank volatility) is the operational symptom of this same underlying weakness. Until the blocked modules are restored, the causal link between citation mix and voice conversion remains directional rather than proven this period.

本章小结

- MixoSense is present in generative responses but under-converts that presence into share-of-voice, with rank placement uneven across prompts — together this describes a visibility-without-authority pattern.
- Citation, content-gap, and competitor benchmarking modules returned no measurable data this period, blocking evidence-backed strategy recommendations until the pipeline is restored and a baseline is established.
- Citation authority is concentrated in academic and patent sources anchored to brand-owned subdomains, creating concentration risk that compounds the voice-conversion gap and should be diversified in the next cycle.
- Two additional diagnostic modules returned no data this period, leaving residual blind spots that should be addressed before the next reporting cycle.

9. GEO 优化策略

本章将上述问题转化为带预期效果的分级行动。

优先级	行动	预期效果	Addresses 问题
P0	Restore the citation data pipeline and re-run the citation sweep to establish a measurable baseline before further optimization work is committed.	Unblocks citation diagnostics, content-gap attribution, and competitive benchmarking, removing the decision-blocking data gap across three modules at once.	ch3 and ch7: citation diagnostics and competitive share-of-voice were not measurable this period, and all configured competitors returned null values.
P0	Diversify the external editorial citation footprint away from the	Reduces authority concentration risk, broadens the source mix that	ch4: high-severity Mixosense-domain concentration creating

	current concentration on brand-owned Mixosense subdomains and academic/patent sources.	generative engines draw from, and protects against single-domain dependency in the answer chain.	authority concentration risk, with citation profile anchored almost entirely in peer-reviewed literature and patent records.
P0	Convert existing generative presence into conversational dominance by improving share-of-voice on the prompts where the brand already appears.	Closes the largest measurable performance gap between appearance frequency and share-of-voice, lifting the brand from present to dominant in cited answers.	ch1: high-severity under-conversion of presence into share-of-voice across generative responses.
P1	Inject brand voice into the citation chain by publishing brand-authored commentary, explainers, and quotable artifacts that can sit alongside academic and patent citations.	Improves brand attribution in generative answers and rebalances authority signals with on-brand narrative, addressing the 'little brand voice in the answer chain' gap.	ch4: high-severity finding that the citation profile carries strong authority signals but minimal brand voice.
P1	Stabilize top-rank placement by tightening the on-page and entity signals that drive first-position outcomes, targeting reduction in rank volatility across prompts.	Raises first-rank frequency and lowers average rank distance, making the brand's positioning in generative answers more predictable and less dependent on prompt wording.	ch1: medium-severity uneven top placement and meaningful volatility in ranking outcomes.
P2	Once the pipeline is restored, re-run the content gap diagnostic so 'content missing' failures can be separated from 'not quotable' failures.	Provides attribution that informs whether to invest in net-new content creation or in restructuring existing content for quotability, eliminating the current attribution blind spot.	ch6: content gap analysis could not be completed this period and currently cannot distinguish content gaps from quotability gaps.

Prioritization is driven by three constraints working in sequence. First, ch3, ch6, and ch7 all returned no usable measurement this period, which means any optimization action cannot be attributed to an outcome until the pipeline is restored; this is sequenced as P0 because it gates every downstream module. Second, the ch4 Mixosense-domain concentration creates a single-point-of-failure risk on the citation side and is compounding because the citation profile leans heavily on academic and patent sources with little brand voice, so diversification and brand-voice injection are paired at P0 and P1 respectively. Third, the ch1 presence-to-dominance gap is the largest identifiable performance gap and offers the most direct conversion lever, warranting P0 focus on share-of-voice conversion. P1 items (brand voice injection, ranking stability) address structural quality issues that only become measurable after the P0 pipeline fix. P2 covers the content-gap re-run, which is fully dependent on P0.

本章小结

- Measurement first: the citation, content-gap, and competitive modules returned no usable data this period, so pipeline repair is the gating P0 that unlocks all downstream attribution.
- Diversify the citation footprint and inject brand voice: the current profile is strong on authority but concentrated on brand-owned Mixosense subdomains and academic or patent sources, creating concentration risk and weak brand attribution.

- Convert presence into dominance: MixoSense appears frequently in generative responses but converts poorly into share-of-voice, the single largest measurable performance gap to attack.
- Sequence matters: P0 unblocks measurement and addresses the two most severe structural risks, P1 addresses secondary quality issues that become measurable once P0 is cleared, and P2 re-runs the content-gap diagnostic on the restored pipeline.

方法说明
